We are pleased to congratulate the candidates who passed the May 2011 FRM $^{\ominus}$ and ERP ${ }^{\oplus}$ Exams.

The FRM designation is the only globally recognized certification for financial risk professionals, and is considered the industry gold FRM designation have demonstrated their mastery of financial risk management practices.

The ERP designation is the new standard in energy risk management, and the first and only professional designation of its kind. Those who have obtained an ERP designation have demonstrated their mastery of both physical and financial energy risk management practices.

D To view a full listing of the new FRM holders, please visit www.garp.org/frm/pass

D To view a full listing of the new ERP holders, please visit www.garp.org/erp/pass

Extending the Large Pool Approximation
How to relax the Vasicek portfolio loss distribution assumptions of an infinite
number of loans and of
the homogeneity of loan
characteristics.
By J. M. Pimbley

Aubiquitous challenge in the financial world is the analysis of the risk of a portfolio of financial instruments.' The basis of structured finance is the specification of an underlying portfolio of risky assets, such as residential and commercial real estate loans and consumer receivables (for credit card and auto loans). The future performance of the underlying portfolio directly determines the performance of the structured finance debt obligations of the transaction that hosts the portfolio. Banks and bank regulators create mathematical models to capital to individual holdings or to entire bank portfolios. ${ }^{2}$ To "assign capital" it is necessary to understand how much reserve to hold against potential loss. Estimation of this reserve requires specification of the cumulative distribution function (CDF) for portfolio loss. Debt ratings for structured finance ransactions also require knowledge of this portfolio CDF. ${ }^{3}$

## asicek Infinite Pool Size Resul

Oldrich Vasicek provided the founding contribution to the deermination of an approximate portfolio CDF for credit losses in a portfolio of debt instruments. ${ }^{4}$ With the assumptions that each loan has identical default probability $p$, size, and loss-given-default (LGD), that each loan has a single asset correlation $\rho(0<\rho<1)$ with every other loan and that the number of loans approaches infinity, Vasicek derived the CDF $F(x)$ to be:
$F(x)=\Phi\left[\frac{-K+\sqrt{1-\rho} \Phi^{-1}(x)}{\sqrt{\rho}}\right]$ with $K \equiv \Phi^{-1}(p) \quad$ (1)

The independent variable $\mathbf{x \epsilon}(0,1)$ in equation (1) is the portfolio loss expressed as a fraction of the total possible loss. The $\operatorname{CDF} \mathrm{F}(x)$ is the probability that the actual (fractional loss will be less than or equal to $x$. By this definition, then, $\mathrm{F}(x)$ is a non-decreasing function of $x$, with and $F(0)=0$ and $F(1)$ $=1 .{ }^{6}$ The symbol $\Phi()$ denotes the standard normal CDF of the quantity within the parentheses while $\Phi^{-1}()$ represents the inverse of this standard normal CDF.
It is helpful to define and construct the probability density function the PDF has an interpe loan loss distribution. Like the CDF $f(x) d x$ is the probability that the portfolio loss will whectel lie in the interval $(x, x+d x)$ as $d x$ approaches zero. The PDF is the derivative of the CDF with respect to the loss fraction $x$ as follows:
$f(x)=F^{\prime}(x)=\sqrt{\frac{1-\rho}{\rho}} \phi\left[\frac{K-\sqrt{1-\rho} \Phi^{-1}(x)}{\sqrt{\rho}}\right] / \phi\left[\Phi^{-1}(x)\right]$
In equation (2), the symbol $\boldsymbol{\phi}()$ denotes the standard normal PDF of the quantity within the parentheses.
Vasicek's equation (1) result is directly useful since it provides the confidence interval for specific potential loan port folio loss amounts. Thus, a bank may apply this $F(x)$ to deter mine economic capital (a key risk measure) of its holdings. A bank regulator may use $F(x)$ to specify the capital ("regulatory capital") it requires banks to hold against a lending portfolio. A rating agency or investor in structured finance debt may us
$F(x)$ to estimate the probability of loss of the debt. $F(x)$ to estimate the probability of loss of the debt.

Warning Regarding the Use of Models
Of course, whether a bank, bank regulator, rating agency, or investor performs this analysis, the result is an approximation, at best, given the restrictive assumptions. First, real loan portfolios do not consist of loans that are all equal in size, default probability and LGD. While it is reasonable to counterpart (witifying a real portfolio to its homogeneous mean LGD) will lead to an adequate approximation for a sufficiently large number of loans, we have no guidance on how "large" this number of loans must be. ${ }^{8}$
Further, even if the loan portfolio already happens to be homogeneous, the Vasicek formulation does not indicate how many loans ( 100 ? 10,000 ? ) the portfolio must have to be well represented by equation (1) - which assumes an infinite number of loans. Finally, the assumption of a single correlation $\rho$
relating all loans is certainly an idealization, but we will retain it.

The contributions of this article are that we remove the constraints of the Vasicek model that the loan portfolio must be homogeneous and infinite. This generalization then allows us to explore the requisite (finite) portfolio size at which the Vasicek approximation becomes reasonably accurate. But he assumptions regarding correlation remain unchanged. This treatment assumes pairwise correlations only. While he reliance on pairwise correlations is standard in the finaninteractions for loan defaults. Further, even within the singlefactor pairwise framework, it is well understood that a single correlation value is not appropriate for all points on the loss distribution. The Vasicek and extended Vasicek solutions we present here are useful tools, but the user should apply them in a manner that recognizes that one correlation value may not provide the best fit to all segments of the loss distribution. A broader statement that applies to the results of this article and to all financial models generally is that one must exercise caution and discretion in the interpretation of the model output. Well-constructed models are best suited as guides to illustrate the dependence of the output (in this case, the portolio capital requirement) on the input data and assumptions such as default probabilities of loans and correlation among oans.) ${ }^{9}$ Uncertainty in the input data necessarily translates to uncertainty in the output results. Hence, decisions regarding capital requirements, credit ratings, investment suitability or other real-world $u$ the model results.

Extended Vasicek Result for a Finite
Homogeneous Pool
The purpose of this communication is to extend the Vasicek results for the CDF and PDF of a loan portfolio - which we also call the Large Pool Approximation (LPA) - to the case of a large (but finite), non-homogeneous portfolio. We consider first the case of a homogeneous portfolio with $\mathcal{N}$ loans with $\mathcal{N} \gg 1$.
We impose correlation among the $\mathcal{N}$ loans in the same manner as Vasicek by positing an asset value $V_{\mathrm{n}}$ for each loan in erms of the correlation $\rho$, as follows:
$V_{n}=\sqrt{\rho} Y+\sqrt{1-\rho} \varepsilon_{n}$
The random variates $Y$ and $\varepsilon_{\mathrm{n}}$ are independent and normally distributed with a mean of zero and a variance of one.
The $V_{\mathrm{n}}$ all share the common factor $Y$, which is the generator
of correlation among the $V_{\mathrm{n}}$. For example, direct calculation from equation (3) shows that $\operatorname{Corr}\left(\mathrm{V}_{i}, V_{j}\right)=\rho$ for $i \neq j$. One may interpret $l$ as "state of the economy," or "home price appre ciation," or "unemployment," depending on the particula loan type one is attempting to approximate.
The asset values $V_{n}$ are themselves normally distributed with a mean of zero and a variance of one. As stated above all pairs of asset values have the same (flat") asset correlaloan ho deep meaning ${ }^{10}$ It is merely a device to impos correlation orrelation
Once constructed in this manner, we determine if a specific loan $i$ has defaulted by comparing $V_{i}$ to $\Phi^{-1}(p)$, where $p$ is the we say the loan is in default.
Beyond providing the desired correlation, equation (3) is useful because it permits us to treat the $\mathcal{N}$ loans as indepen dent once we have fixed the value of 1 . Following the well trod path of Vasicek and others, ${ }^{11}$ we analyze the portfolio loan loss distribution for a fixed $Y$ and then integrate over all pos sible values of $\mathcal{C}$. The probability $f_{n}$ that exactly $n$ of $\mathcal{N}$ loan will default, given a default probability of $\beta$, is ${ }^{12}$

$$
\begin{equation*}
\tilde{f}_{n}=\binom{N}{n} \hat{p}^{n}(1-\hat{p})^{N-n} \tag{4}
\end{equation*}
$$

At this point the Vasicek method invokes the "law of larg numbers" to stipulate that the number of defaults $n$ will equa $\beta$ of all loans default.
$=\phi, N$ is the step in the current LPA derivation that requires $=p \mathcal{N}$ is the step in the current LPA derivation that requires $\mathcal{J}$
to be infinite. We propose here an improvement that approximates equation (4) for large, but finite, $\mathcal{N}$. By applying Stirling's approximation ${ }^{13}(\log \mathcal{N}!\approx \mathcal{N} \log \mathcal{N}-\mathcal{N}+1 / 2 \log 2 \pi \mathcal{N}$, where "log" denotes the natural logarithm) to the factorial terms of (4), we derive the new approximation, ${ }^{14}$ as follows:

$$
\tilde{f}_{n}=\binom{N}{n} \hat{p}^{n}(1-\hat{p})^{N-n} \approx
$$

$[2 \pi \hat{p}(1-\hat{p}) N]^{-1 / 2} \exp \left[-N(x-\hat{p})^{2} / 2 \hat{p}(1-\hat{p})\right], N \gg 1$
with $x=n / N$

Since $\mathcal{N}$ is large, we can consider $x$ to be a continuous variable, because the separation between permissible values of $x$ is $1 / \mathcal{N}$. The conversion from the probability function $\widetilde{f}_{n}$ to the PDF $\hat{f}(x)$ for the continuous variable $x$ is $\hat{f}(x)=N \widetilde{f}$. We use the "hat" notation in $f(x)$ to indicate that this PDF still assumes (or is conditioned on") a specific value of the common factor $r$ From equation (5), then, we get
$\hat{f}(x)=\left[\frac{N}{2 \hat{p}(1-\hat{p})}\right]^{1 / 2} \exp \left[-N(x-\hat{p})^{2} / 2 \hat{p}(1-\hat{p})\right]$
Equation (6) is convenient and intuitive in that it is a normal density function. Hence, it is entirely consistent with the
Central Limit Theorem and it approaches a Dirac delta function as $\mathcal{N} \rightarrow \infty$. The Vasicek LPA is this Dirac limit. ${ }^{15}$ Hence, our extension of the Vasicek LPA is simply the substitution of equation (6) for the Dirac delta function.
With $f(x)$ from equation (6), we've determined the PDF for a given value of $r$. Recall that equation (3) gives the default behavior of each of the $\mathcal{N}$ loans. We now impose the asset correlation $\rho$ to give us the correlated loan default $\operatorname{PDF} f(x)$ by integrating $\hat{f}(x)$ over all possible values of the normally distributed $Y$, as follows

$$
\begin{equation*}
f(x)=\int_{-\infty}^{+\infty} d y \phi(y) \hat{f}(x) \tag{7}
\end{equation*}
$$

As before, $\phi_{( }$) is the standard normal PDF. Equation (6) shows that $\hat{f}(x)$ depends on $y$ through the default probability $f$ which we clarify here to be
$\hat{p}=\Phi\left(\frac{K-\sqrt{\rho} y}{\sqrt{1-\rho}}\right)$
with K already defined in equation (1).
Applying a change of variable to the integral in equation (7), we find
$f(x)=\left(\frac{N}{2 \pi}\right)^{1 / 2} \int_{0}^{1} d u \frac{\exp \left[-N(x-u)^{2} / 2 u(1-u)\right]}{\sqrt{u(1-u)}} f_{\infty}(u) \quad$ (9)
The notation $f_{x}()$ represents the $(\mathcal{N} \rightarrow \infty)$ Vasicek LPA expression that we stated in equation (2) and copy here:
$f_{\infty}(x)=\sqrt{\frac{1-\rho}{\rho}} \phi\left[\frac{K-\sqrt{1-\rho} \Phi^{-1}(x)}{\sqrt{\rho}}\right] / \phi\left[\Phi^{-1}(x)\right] \quad$ (10)
To get the CDF for the portfolio loss distribution, we go back to equation (7) and apply the property $F(x)=\int_{0}^{x} d t f(t)$
to find
$F(x)=\int_{-\infty}^{+\infty} d y \phi(y) \Phi\left[\frac{x-\hat{p}}{\sqrt{\hat{p}(1-\hat{p}) / N}}\right]$
Applying the same change of variable that produced equation (9), we write

$$
\begin{equation*}
F(x)=\int_{0}^{1} d u \Phi\left[\frac{x-u}{\sqrt{u(1-u) / N}}\right] f_{\infty}(u) \tag{11}
\end{equation*}
$$

An unfortunate aspect of both equations (9) and (11) is that they require numerical integrations. These forms do not easily show the reader how different these extended LPA ("XLPA")
results differ from the LPA $(N \rightarrow \infty)$ counterparts. To reduce results differ from the LPA $(\mathcal{N} \rightarrow \infty)$ counterparts. To reduce
this difficulty, we recast equation (10) into the following less compact but more insightful form:
$F(x)=F_{\infty}(x)+\int_{0}^{1} d u\left\{\Phi\left[\frac{x-u}{\sqrt{u(1-u) / N}}\right]-H(x-u)\right\} f_{\infty}(u) \quad$ (12)
In equation (12), $H()$ is the Heaviside function ${ }^{16}$ and $F_{\propto}(x)$ is
the LPA CDF, which we wrote in equation (1) and reproduce the LPA CDF, which we wrote in equation (1) and reproduce here, as follows:
$F_{\infty}(x)=\Phi\left[\frac{-K+\sqrt{1-\rho} \Phi^{-1}(x)}{\sqrt{\rho}}\right]$
Granularity Adjustment
The integral term of equation (12) is the difference between the CDFs for the LPA and for the XLPA (which permits the number of loans $\mathcal{N}$ to be finite). Numerous studies over the past years have investigated this difference and given it the
descriptive term "granularity adjustment" (GA). ${ }^{17}$ These studies did not derive and evaluate the integral in equation (12); rather, they have developed asymptotic representations of the GA in powers of $1 / \mathcal{N}$.
We believe results of this existing analysis are consistent with this new XLPA result. For example, one can show by direct analysis that the difference between $f(x)$ and $f_{0}(x)$ in equation (9) is $O\left(1 / \mathcal{M}\right.$ ). Since $F(x)=\int d t f(t)$, the difference between $F(x)$ and $F_{\infty}(x)$ and would also behave as $O(1 / \mathcal{M})$ for large $\mathcal{N}$. Numerical evaluations of equation (12) confirm this behavior.
Comparison of the LPA and XLPA
Figures la and 1b compare the PDF for the LPA (equation (10)) with the PDF for various values of the number of loans $\mathcal{N}$ for the XLPA (equation (9)), with a loan default probability
of $10 \%$ and an (asset) correlation of $5 \% .^{18}$

Figure 1a: PDF for 10\% PD and 5\% Correlation

Figure 1b: PDF for 10\% PD and 5\% Correlation

Figure la specifies a linear y -axis while figure lb is loea Frgure la specifies a linear $y$-axis while figure 1 b is loga-
rithmic in order to see the extended tail as the loss fraction rithmic in order to see the extended tail as the loss fraction
x increases. The XLPA PDF with 10,000 loans is visually indistinguishable from the LPA PDF. With 1,000 loans, the difference between the XLPA and LPA is visible; while for 100 loans, the difference is significant. Roughly speaking, then, the LPA is a good approximation to a finite loan pool of 1,000 loans or greater with default probability of $10 \%$ and correlafion of $5 \%$. The LPA is not a good approximation when there are only 100 loans.
Figures 2a and 2b (see pg. 18) change the correlation from $5 \%$ to $20 \%$. The shapes of the curves change considerably, with the peak of the PDF moving to lower values of loss fraction and the high-loss-fraction tail increasing. Yet the LPA appears to become a better approximation with higher correlation (all else being equal).

Figure 2a: PDF for 10\% PD and 20\% Correlation

Figure 2b: PDF for 10\% PD and 20\% Correlation

## Extended Vasicek Result for a Finite

Non-homogeneous Pool
To this point, the XLPA has simply extended the LPA result to the case of a finite number of loans, while still requiring the homogeneity of uniform loan size, default probability, and LGD. Relaxing this last requirement for these portfolio pa-
rameters is not as challenging as it may seem, as long as the pool remains reasonably diversified.
Consider the result in equation (6) for the homogeneous pool loss $\operatorname{PDF} \hat{f}(x)$ given a fixed value of the common factor $\Upsilon$. This PDF is a normal density function with mean $\beta$ and standard deviation $\sqrt{\hat{p}(1-\hat{p}) / N}$, which we will define as $\sigma$. While
we cannot directly derive the PDF for the non-homogeneous we cannot directly derive the PDF for the non-homogeneous
pool, we can derive the mean and standard deviation of this
unknown PDF and find: ${ }^{19}$
Mean $=\sum L_{i} \hat{p}_{i} \lambda_{i} / \sum L_{i} \lambda_{i}$
(14a)
Standard Deviation $=\left[\sum_{i} L_{i}^{2} \lambda_{i}^{2} \hat{p}_{i}\left(1-\hat{p}_{i}\right)\right]^{1 / 2} / \sum_{i} L_{i} \lambda_{i}(14 \mathrm{~b})$
In equations (14a) and (14b), $L_{i}, \lambda_{i}, p_{i}$ and are the known par amount, assumed LGD and specified default probability, respectively, for loan $i$, with $i$ ranging from 1 to $\mathcal{N}$. As Appenvalue of $\sqrt{\hat{p}(1-\hat{p}) / N}$ in the special case that all the $L_{i}, \lambda_{i}$ and $\beta_{i}$ equal the common values of $L, \lambda$ and $\beta$ respectively, as one would expect.
Let us define the non-homogeneous pool PDF to be $\hat{f}_{m u}(x)$. The mean of $f_{t_{k}}(x)$ is $\beta$ - the same as the mean of the homogeneous pool PDF $f(x)$ - since we define $\beta$ for the nonhomogeneous portfolio to be the weighted average in equaion (14a). The standard deviation of $f_{n k}(x)$ will, in general, be larger than that of $f(x)$ for the homogeneous pool of the same size $\mathcal{N}$ and mean values of $L, \lambda$, and $p$. For convenience, then, we write the standard deviation of $\hat{f}_{m_{u}}(x)$ as $\gamma \sqrt{\hat{p}(1-\hat{p}) / N}$ where, from equation (14b), we find
$\gamma=\left[\frac{N}{\hat{p}(1-\hat{p})} \sum_{i} L_{i}^{2} \lambda_{i}^{2} \hat{p}_{i}\left(1-\hat{p}_{i}\right)\right]^{1 / 2} / \sum_{i} L_{i} \lambda_{i}$
Given an actual loan portfolio, it is straightforward to compute the numerical value of $\gamma$ from equation (15).
The probability density function resulting from the addition of a large number of independent contributions approaches a normal density function. ${ }^{20}$ Just as we required the number of
loans $\mathcal{N}$ to be large so that equation (6) provided a form of the homogeneous pool PDF $\hat{f}(x)$ more useful than that of equation (4), the large $\mathcal{N}$ requirement permits us to specify the nonhomogeneous pool PDF $f_{\text {mu }}(x)$ as the normal density function with desired mean and standard deviation, as follows:
$\hat{f}_{n k}(x)=\frac{1}{\gamma}\left[\frac{N}{2 \hat{p} \hat{p}(1-\hat{p})}\right]^{1 / 2} \exp \left[-N(x-\hat{p})^{2} / 2 \gamma^{2} \hat{p}(1-\hat{p})\right]$ (16)
In other words, solving the non-homogeneous pool problem is not difficult. One need only compute the $\boldsymbol{\gamma}$ value from the actual portfolio parameters and modify the XLPA expressions we derived previously. The only qualification is that, just
like the original Vasicek LPA, there exists no clear guideline on how large $N$ must be for the vague constraint "large $N$ " to must be for the vague constraint "large $\mathcal{N}$ " to be satisfied.

Solving the non-homogeneous pool problem is not difficult. One need only compute the $\gamma$ value from the actual portfolio parameters and modify the XLPA expressions we derived previously.
As a trivial example, we found earlier that 10,000 loans As a trivial exaicitly large pool for the Vasicek LPA to constitute a sufficiently large pool for the Vasicek LPA to
be valid for the homogeneous pool with the parameters we be valid for the homogeneous pool with the parameters we
specified. (In fact, the single greatest attribute of the XLPA is specified. (In fact, the single greatest attribute of the XLPA is
simply that it provides a check on the LPA.) Suppose we now add just one additional loan with par amount equal to that of the entire pre-existing portfolio.
Even if the LGD and default probability of this new loan equal those of the other loans, this is a huge non-homogeneity! In this extreme case, the PDF of the loss for this 10,001loan portfolio would not be well approximated by a normal density function. Hence, equation (16) would not be appropriate. Rather, equation (16) would only become appropriate for a much larger number of loans if this type of extreme par amount idiosyncrasy is present.
Just as equation (16) extends the equation (6) homogeneous PDF to the case of a more realistic non-homogeneous portfo-
lio, we give the extensions to equations $(9)$, (11), and (12), for the final PDF and CDF results, as

$$
\begin{gather*}
f_{n h}(x)=\left(\frac{N}{2 \pi}\right)^{1 / 2} \int_{0}^{1} d u \frac{\exp \left[-N(x-u)^{2} / 2 \gamma^{2} u(1-u)\right]}{\gamma \sqrt{u(1-u)}} f_{\infty}(u)  \tag{17}\\
F_{n h}(x)=\int_{0}^{1} d u \Phi\left[\frac{x-u}{\gamma \sqrt{u(1-u) / N}}\right] f_{\infty}(u) \tag{18}
\end{gather*}
$$

$F_{n h}(x)=F_{\infty}(x)+\int_{0}^{1} d u\left\{\Phi\left[\frac{x-u}{\gamma \sqrt{u(1-u) / N}}\right]-H(x-u)\right\} f_{\infty}(u) \quad$ (19)
The functions $f_{\infty}()$ and $F_{\infty}()$ retain their earlier meanings as the PDF and CDF, respectively, of the Vasicek LPA.

## FOOTNOTES

1. What we now call "modern portfolio theory" dates back to the
seminal work of Harry Markowitz See H. M. Markowitz "Portoseminal work of Harry Markowitz. See H. M. Markowitz, "Portfo-
lio Selection," The Jourral of Finance 7(1), 77-91, March 1952. See also H. M. Markowitz, Portfolo Selection: Effcient Diversification of Investments, John Wiley \& Sons, 1959.
2. See, for example, M. B. Gordy, "A Risk-Factor Model Foundation for Ratings-Based Bank Capital Rules," 7 . Financial Intermediation 12, 199-232, 2003.
3. See, for example, DBRS, Inc., "Master European Granular Corporate Securitisations (SME CLOs)," June 2011, at http://dbrs.

Credit Deriuatives Pricing Models, John Wiley \& Sons Ltd., 2003.
5. The total possible loss is the sum over all portfolio loans of the product of loan size and loan LGD.
6. As a qualification to this statement, it is possible for $F(0)$ to be greater than zero if we permit discontinuous density functions.
The interpretation of such a positive value is simply that there is a non-zero probability that the portfolio loss is precisely zero.
7. See, for example, P. S. Calem and J. R. Follain, "The AssetCorrelation Parameter in Basel II for Mortgages on Single-Family Residences," Back ground for Public Comment on the Advanced Noticic of
Proposed Rulemaking on the Proposed New Basel Capital Accord, Board of Proposed Rulemaking on the Proposed New Basel Capital Accord, Board of Governors of the Federal Reserve System, November 2003
8. Non-homogeneous loan portfolios have arbitrary distributions of loan size, default probability and LGD. The nature of these distributions will impact whether the homogeneous counterpart
provides a reasonable approximation for a specific, large number provides a reasonable approximation for a specific, large number
of loans. The substitution of "mean" values to create the homogeof loans. The substitution of "mean" values to create the homoge-
neous portfolio will need to employ suitably weighted means.
9. In this role, models serve as excellent tests of data quality sinc erroneous input data often present vividly in the model output.
10. I's likely that the Merton model for investigating the default probability of a corporate entity's debt motivated Vasicek's treatment. In the Merton approach, the "asset value" really does repre--
sent something close to the value of the assets of the firm. But this sent something close to the value of the assets of the firm. But this background thought process is not necessary
11. Up to this point, we are recounting the discussion the reader
will find in O Vasicek, "Probability of will find in O. Vasicek, "Probability of Loss on Loan Portfolio,"

## Appendix A

Beginning with equation (4), we seek to use Stirling's approximation to derive equation (5). Taking the natural logarithm of both sides of (4), we find

$$
\log \widetilde{f}_{n}=\log \left[\binom{N}{n} \hat{p}^{n}(1-\hat{p})^{N-n}\right]
$$

$\log N!-\log n!-\log (N-n)!+n \log \hat{p}+(N-n) \log (1-\hat{p}) .(\mathrm{A} 1)$

## Applying

$$
\log N!\approx N \log N-N+\frac{1}{2} \log 2 \pi V
$$

to the first term of (A1) and similar approximations to the other log- factorial terms, we find
$\frac{1}{N} \log \tilde{f}_{n} \approx(1-x) \log \frac{1-\hat{p}}{1-x}+x \log \frac{\hat{p}}{x}-\frac{1}{2 N} \log [2 \pi x(1-x) N]$. (A2)
In (A2), we eliminated $n$ by replacing it with $\mathcal{N} x$, so that $x$ is the loss fraction. Both $\beta$ and $x$ have values in the range $(0,1)$. Inspection of the first two terms on the right-hand side of (A2) shows a maximum value of zero at $x=\beta$ with local quadratic behavior, as follows:
$(1-x) \log \frac{1-\hat{p}}{1-x}+x \log \frac{\hat{p}}{x} \approx \frac{-(x-\hat{p})^{2}}{2 \hat{p}(1-\hat{p})}$ for $x$ near $\hat{p}$. (A
We neglected the $\log x(1-x)$ term in (A2) for purposes of approximating the $x$-dependence since this term is divided by $\mathcal{N}$, which makes it small relative to the first two terms. The result as follows, the exponential of a large (since multiplied by $M$ and negative quadratic function:
$\tilde{f}_{n} \approx[2 \pi \hat{p}(1-\hat{p}) N]^{-1 / 2} \exp \left[-N(x-\hat{p})^{2} / 2 \hat{p}(1-\hat{p})\right]$. (A4)
Equation (A4) is identical to equation (5) which is what we sought to prove. To get (A4), we made one other approximation. We replaced $x(1-x)$ by $\beta(1-\beta)$ in the term preceding the exponential. The justification for this replacement is that the exponential term in (A4) will make $\widetilde{f}_{n}$ very small for any value of $x$ not sufficiently close to $\oint$, given that these approximations are reasonable only for $\mathcal{N} \gg 1$. The replacement is extremely tional form for $\begin{array}{r}n \\ n\end{array}$ and the correct normalization for $\widetilde{f}(x)$ in equation (6) as a PDE

## Smarter technology for a Smarter Plane

## Finding meaning in the noise.

An unprecedented amount of information flows through companies every day. But to what effect?
A recent study found that $52 \%$ of managers don't have confidence in the information they rely on to do their job. Without the right approach to business intelligence, companies are struggling to turn all that information into sound decisions. IBM business intelligence and performance management solutions give you the smarter tools you need to access the right information, making it available to the right people, when and how they need it. Today IBM is helping over 20,000 companies spot trends, mitigate risk and make better decisions, faster.
A smarter business needs smarter software, systems and services.
Let's build a smarter planet. ibm.com/intelligence

Let's consider how the standard deviation expression for a non-homogeneous loan portfolio (equation (B5)) changes when we make all loan par amounts equal $\left(L_{i} \rightarrow L\right)$, all LGD values equal $\left(\lambda_{i} \rightarrow \lambda\right)$, and all default probabilities equal ( $\left.p_{i} \rightarrow p\right)$. The denominator of (B5) becomes NLD while the summation in the numerator becomes $\mathcal{N} L^{2} \lambda^{2} \beta(1-\beta)$.

## Appendix B

Our goal is to derive the mean and standard deviation of the fractional loss of a non-homogeneous portfolio, as shown in equations (14a) and (14b), respectively. With $\mathcal{N}$ loans of par amount $L_{i}$, loss-given-default (LGD) $\lambda_{i}$ and default probability
$p_{i}$, the portfolio loss is

$$
\text { Loss }=\sum_{i} L_{i} \lambda_{i} \varepsilon_{i}
$$

(B1)
In (B1), the $\varepsilon_{i}$ term equals 1 (probability $p_{i}$ ) when loan $i$ is in default and zero (probability $1-p_{i}$ ) otherwise. All summation range from 1 to $\mathcal{N}$. The expected loss is
$E\{$ Loss $\}=E\left\{\sum_{i}^{L} L_{i} \lambda_{i} \varepsilon_{i}\right\}=\sum_{i} L_{i} \lambda_{i} E\left\{\varepsilon_{i}\right\}=\sum_{i} L_{i} \lambda_{i} \hat{p}_{i}$ $\qquad$
Dividing this expected loss by the total possible loss of $\sum_{i} L_{i} \lambda_{i}$, we find the expected loss fraction is precisely the expression in (14a).
To get the standard deviation of the loss fraction (14b), we must first find the variance of the portfolio loss, which leads us to determine the expected square of the loss, as follows

$$
\begin{gathered}
E\left\{\operatorname{Loss} s^{2}\right\}=E\left\{\sum_{i, j} L_{i} L_{j} \lambda_{i} \lambda_{j} \varepsilon_{i} \varepsilon_{j}\right\}=\sum_{i, j} L_{i} L_{j} \lambda_{i} \lambda_{j} E\left\{\varepsilon_{i} \varepsilon_{j}\right\} \\
=\sum_{i} L_{i}^{2} \lambda_{i} \hat{p}_{i} \hat{x}_{i}+\sum_{i \neq j} L_{i} L_{j} \lambda_{i} \lambda_{j} \hat{p}_{i} \hat{p}_{j} .
\end{gathered}
$$

Since the variance of the loss is the expectation of the quared loss minus the square of the expected loss, we use (B2) and (B3) to write

$$
\operatorname{Var}\left\{L_{\text {oss }}\right\}=E\left\{\text { Loss }^{2}\right\}-[E\{\text { Loss }\}]^{2}
$$

$$
=\sum_{i} L_{i}^{2} \lambda_{i}^{2} \hat{p}_{i}+\sum_{i \neq j} L_{i} L_{j} \lambda_{i} \lambda_{j} \hat{p}_{i} \hat{p}_{j}-\sum_{i, j} L_{i} L_{j} \lambda_{i} \lambda_{j} \hat{p}_{i} \hat{p}_{j}
$$

$$
=\sum_{i} L_{i}^{2} \lambda_{i}^{2} \hat{p}_{i}\left(1-\hat{p}_{i}\right)
$$

Taking the square root of this variance to get the standard deviation of the portfolio loss and then dividing by the total possible loss $\sum_{i} L_{i} \lambda_{i}$, we find the standard deviation of loss fraction to be

$$
=\left[\sum_{i} L_{i}^{2} \lambda_{i}^{2} \hat{p}_{i}\left(1-\hat{p}_{i}\right)\right]^{1 / 2} / \sum_{i} L_{i} \lambda_{i} \quad \text { (B5) }
$$

## which is identical to (14b)

As a final exercise, let's consider how the standard deviaion expression for a non-homogeneous loan portfolio (equaion (B5)) changes when we make all loan par amounts equal $\left(L_{i} \rightarrow L\right)$, all LGD values equal $\left(\lambda_{i} \rightarrow \lambda\right)$, and all default probabilities equal $\left(p_{i} \rightarrow \beta\right.$ ). The denominator of (B5) becomes $N L \lambda$ while the summation in the numerator becomes $N L^{2} \lambda^{2} \beta(1-\beta)$. Consequently, taking the square root of this term and dividing by the denominator, we find the standard deviation of loss fraction for the "homogeneous portfolio limit" to be $\sqrt{\hat{p}(1-\hat{p}) / N}$, portforio cosponds to our earlier results for the homogeneous portfolio.
